Hydroxyproline-rich glycoproteins (HRGPs) accumulation and oxidative cross-linking is one of the earliest defense responses in plants against pathogen infection. In the present study HRGP accumulation in three sorghum genotypes i.e. SC146 (resistant), SC326 (intermediately resistant) and BTx623 (susceptible) as a response to Colletotrichum sublineolum isolate CP2126 infection is elucidated. HRGPs were monitored by hydroxyproline (Hyp) estimation. In genotypes SC146 and SC326 there was a significantly higher amount of Hyp at 2 days after inoculation (dai) compared to genotype BTx623, indicating an infection induced accumulation of HRGPs. Western blot analysis of acid-ethanol extracted proteins with polyclonal antibody raised against pearl millet purified HRGPs identified four bands with molecular masses of 65, 45, 17 and 14 kDa as HRGPs. Insolubilization of the 45 kDa protein in genotypes SC146 and SC326 upon infection with C. sublineolum indicates a role of this protein in cell wall cross-linking, coinciding with heavier accumulation of hydrogen peroxide. In addition, tissue print analysis using polyclonal antibody of pearl millet HRGPs recognized these cross-linked proteins to be HRGPs. These findings indicated that HRGPs in sorghum is a component of defense reaction against C. sublineolum infection.

Keywords: sorghum anthracnose; disease resistance; hydroxyproline-rich glycoproteins; hydroxyproline; hydrogen peroxide

Introduction

Plant cell walls are dynamic structures that vary in their composition depending on their age, type of tissues and taxonomical plant group. Furthermore, they change with physiological fluctuations and after external stimuli from environment (Bradley et al. 1992). The most abundant structural proteins in plant cell walls are the hydroxyproline rich glycoproteins (HRGPs). They are induced as defense responses, specifically in incompatible plant-pathogen interactions (Davis et al. 1997). Functionally, there is evidence that HRGPs act as impenetrable physical barriers against pathogen ingress and that they immobilize the pathogens by binding to their negatively charged surfaces (Leach et al. 1982; Mazau et al. 1987; Cassab and Varner 1988). HRGPs include extensins, arabinogalactan proteins (AGPs), proline/hydroxyproline-rich proteins (P/HRGPs), and solanaceous lectins (Sommer-Knudsen et al. 1998). Among these, the P/HRGPs and extensins are known to be insoluble proteins whereas AGPs are soluble. Most of the earlier studies on infection-induced accumulation of HRGPs were carried out in dicotyledons, e.g. French bean infected with Colletotrichum lindemuthianum (Templeton et al. 1990; Millar et al. 1992; Bindschedler et al. 2006), lettuce infected with Pseudomonas syringae (Bestwick et al. 1995), French bean infected with Xanthomonas campestris (Brown et al. 1998) and tobacco leaves infected by Erysiphe cichoracearum (Raggi 2000). In recent years, reports have emerged on the accumulation of HRGPs in monocotyledons as a response to pathogens, e.g. in pearl millet with Sclerospora graminicola (Shailasree et al. 2004), in wheat infected by Fusarium culmorum (Kang and Buchenauer 2003) and in maize treated with a Fusarium moniliforme-derived elicitor (Garcia-Muniz et al. 1998).

The oxidative cross-linking of cell wall structural proteins is thought to be a rapid defense response to strengthen the cell wall against the invading pathogen prior to the activation of other post-transcription-dependent defense responses such as accumulation of pathogenesis-related proteins (PR-proteins) and defense genes expression (Bradley et al. 1992; Brisson et al. 1994). This oxidative cross-linking at the cell surfaces following fungal infection is known to be driven by peroxidases and H₂O₂, which rapidly accumulates from an oxidative burst (Brisson et al. 1994; Ribeiro et al. 2006). HRGPs cause cell wall strengthening by the formation of intra- and inter-molecular cross-links resulting in their rapid insolubilization in cell walls. The cross-linking

Three sorghum genotypes, i.e. SC146 (Host, pathogen, inoculation and sampling Materials and methods

**Colletotrichum sublineolum** P. Hen. in Kabat et Bub. infects all aerial parts of the sorghum plant causing the anthracnose. The pathogen is classified as a hemibiotroph, with an initial, symptomless biotrophic phase, with thick intracellular primary hyphae. This is followed by development of inter- and intracellular thin necrotrophic secondary hyphae (Wharton and Julian 1996; Wharton et al. 2001). Recently, we studied the infection biology and initial defense responses including induction of peroxidase activity and ROS accumulation in response to *C. sublineolum* infection in three genotypes of sorghum varying in resistance to the pathogen (P. Basavaraju, N.P. Shetty, H.S. Shetty, E. de Neer-gaard and H.J.L. Jorgensen, unpublished results). The present study is directed towards elucidation of a role for HRGPs in resistance of sorghum against *C. sublineolum* infection, leading to cell wall strengthening, against pathogen ingress.

**Materials and methods**

**Host, pathogen, inoculation and sampling**

Three sorghum genotypes, i.e. SC146 (=Inbred Stock 12637), SC326 (=Inbred Stock 3758) and BTx623, resistant, intermediate resistant and susceptible, respectively, to *Colletotrichum sublineolum* isolate CP2126 were used throughout the study. Sorghum plants grown in the 9" earthen pots filled with a mixture of soil:sand:manure (1:1:1) under greenhouse conditions with 12/12 light and darkness, respectively. Relative humidity (RH) was maintained approximately at 80 and 60% in day and night, respectively, and temperatures of 27 and 25°C in day and night, respectively. *Colletotrichum sublineolum* isolate CP2126, originally isolated from cv. TAM 428 (=CP 1943) by C.R. Casela (Embrapa Milho e Sorgo, Sete Lagoas, Brazil), was grown on Potato Dextrose Agar (Hi-Media) at 22°C in day and 18°C in night. Five gram leaf tissue of distilled water treated and pathogen inoculated plants at each time point were used for cell walls preparation and extraction of Hyp according to the procedures of Shailasree et al. (2004). Hyp content was expressed as µg Hyp mg⁻¹ cell wall (dry weight).

**Protein isolation and Western blotting**

Cell walls from the leaves of sorghum seedlings were obtained by modifying the procedure of York et al. (1986). Total cell wall proteins were extracted following the procedure described by Leach et al. (1982) and Shailasree et al. (2004). Proteins were subjected to 12% SDS PAGE. Total proteins in the extract were stained with Coomassie blue. For Western blot analysis the separated proteins were blotted onto polyvinylidene difluoride (PVDF) membrane according to the procedures of Shailasree et al. (2004). The blots were blocked in 2% fat-free milk in Tris-buffered saline (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl). Then they were probed with pAB-P/HRGP (1:1000 dilution), a rabbit polyclonal antibody raised against pearl millet P/HRGPs (Deepak et al. 2007a). Subsequently, the blots were incubated with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl), the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were incubated with DAB staining apparatus according to the manufacturer’s protocol. The blots were blocked in 2% fat-free milk in Tris-buffered saline (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl). Then they were probed with pAB-P/HRGP (1:1000 dilution), a rabbit polyclonal antibody raised against pearl millet P/HRGPs (Deepak et al. 2007a). Subsequently, the blots were incubated with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature. After washing twice with TBST (TBS: 10 mM Tris HCl, pH 8.0 containing 150 mM NaCl, 0.05% Tween 20) for 5 min each, the blots were stained with anti-rabbit IgG horseradish peroxidase-conjugate (1:1000 dilution) for 1 h at room temperature.
by following the method described by Shetty et al. (2003).

**Tissue printing**

Tissue printing was done as described by Cassab and Varner (1987). Four replicates of four cross-sections each of the inoculated and control leaves of SC146, genotypes SC326 and genotypes BTx623 leaves were printed. Leaf samples harvested 2 dai were cross-sectioned, dried on a Kimwipe, and pressed onto a nitrocellulose membrane for 15 sec. The nitrocellulose was previously soaked in 0.2 M CaCl₂ for 15 min and air-dried. Serial prints were made and stained with Coomassie blue for determination of total protein content.

A parallel set of sections was subjected to immunolabelling with pAB-P/HRGPs. For this the blots were blocked by 3% BSA in TBST for 1 h. They were then treated with a 1:5000 dilution of primary antibody (pAB-P/HRGPs) for 1 h and washed three times with TBST for 10 min each. The blots were later treated with 1:1000 diluted secondary antibody conjugated with horseradish peroxidase and washed three times for 10 min each in TBST. Blots were developed by using DAB and H₂O₂ and were observed under a stereo microscope (Leica MS5, Germany) at high magnification with light provided from above. Images were recorded with a digital camera (Canon Power Shot S50) attached to the stereomicroscope and processed using Photoshop 8.0.1 (Adobe).

**Statistical analysis**

Data from studies of Hyp estimation represent continuous variables, which were analyzed by analysis of variance assuming a normal distribution. Hypotheses were rejected at \( p \leq 0.05 \). Data were analyzed by PC-SAS (release 8.2; SAS Institute, Cary, NC). The Hyp estimation experiment was repeated three times with two replicates each, whereas all the other experiments were performed at least twice. Only representative data are presented.

**Results**

**Accumulation pattern of HRGPs in sorghum in response to C. sublineolum infection**

The accumulation pattern of HRGPs, as determined by a time course study of Hyp content in the cell walls of the resistant (SC146), the intermediately resistant (SC326) and the susceptible (BTx623) genotypes of sorghum in response to *C. sublineolum* infection is seen in Figure 1. There were no significant differences in Hyp content between the inoculated and control plants of either of the three genotypes at 0 and 1 dai. However, at 2 and 3 dai, a significantly higher Hyp content was recorded in all the three genotypes inoculated with the pathogen compared to their distilled water controls (Figure 1a–1c). Furthermore, genotypes, SC146 and BTx623 displayed significantly higher Hyp content until 5 dai (Figure 1a–1c), whereas genotype SC326 did not accumulate significant amounts of Hyp at the later time points (4 and 5 dai) (Figure 1b).

**Analysis of acid-ethanol extracted proteins and Western blot analysis of HRGPs**

Coomassie blue staining of SDS-PAGE separated proteins revealed a number of resolved proteins with molecular weights ranging from \( \sim 65 \) to 7 kDa (data not shown).

Four proteins corresponding to \( \sim 65, 45, 17 \) and 14 kDa were detected on the western blots using pearl millet pAB-P/HRGPs polyclonal antibodies

![Figure 1](image_url)
A small induction in the ~17 and 14 kDa proteins was observed after inoculation with the pathogen in leaf samples of the resistant, intermediate resistant and susceptible genotypes. Band intensity analysis also showed a small induction of the ~17 and 14 kDa proteins in infection (Figure 2b). The ~45 kDa protein was detected in the controls of the resistant and intermediate resistant genotypes, but not in *C. sublineolum* infected samples of these genotypes. However, although this protein band was positively detected genotypes in both control and *C. sublineolum* inoculated plants of the susceptible genotype BTx623.

Absence of the ~45 kDa protein in the inoculated resistant and intermediate resistant genotypes but not in the susceptible genotype was also analyzed by the Bioprofile Image Analysis System (Figure 2b). The ~65 kDa protein was observed with low intensity in the inoculated samples and control samples of all the three genotypes.

### H$_2$O$_2$ accumulation at host-pathogen interaction sites

At sorghum-*C. sublineolum* interaction sites, a dark reddish-brown staining by DAB indicated H$_2$O$_2$ accumulation at 2 dai, mostly at cell walls and in the apoplastic spaces. H$_2$O$_2$ accumulation was seen in one to several cells around the infection sites. Accumulation of H$_2$O$_2$ was predominant in and around the infection structures like appressoria and infection vesicles (Figure 3a) in the resistant genotype SC146, whereas, in the susceptible genotype BTx623 lack of accumulation correlated with pathogen growth (Figure 3b).

### Tissue printing of HRGPs

Tissue print analysis with pAB-P/HRGPs of cross sections of leaves harvested from the three genotypes, at 2 dai are shown in Figure 4. The total protein content was stained with Coomassie blue in order to show the equal basal level of protein in the resistant genotype SC146 not inoculated (Figure 4A) and
inoculated (Figure 4C), in the intermediately resistant genotype SC326 not inoculated (Figure 4E) and inoculated (Figure 4G) and in the susceptible genotype BTx623 not inoculated (Figure 4I) and inoculated (Figure 4K). Both in the resistant genotype SC146 and intermediately resistant genotype SC326, inoculated (Figure 4D and H) leaves showed a higher level of HRGP in the epidermal region as well as in the vascular tissues when compared to the distilled water treated controls (Figure 4B and F). In the susceptible genotype BTx623, there was no such HRGP accumulation either in controls (Figure 4J) or in inoculated samples (Figure 4L).

**Discussion**

The present study was undertaken to investigate the possible involvement of HRGPs in the defense response of sorghum against infection by the pathogen *C. sublineolum* (isolate CP2126) infection. The time-course study on accumulation of HRGPs was determined by monitoring the Hyp content in the cell walls. The colorimetric estimation of Hyp is reported to be a sensitive indicator for the presence of HRGPs (Raggi 2000). The analysis of Hyp indicates that the level of wall-bound HRGPs was higher in the leaves of the resistant genotype SC146 and intermediately resistant genotype SC326 than in the susceptible genotype BTx623. A marked increase in the level of these proteins was observed in the genotypes SC146 and SC326 following inoculation with *C. sublineolum*. These results confirm and extend several previous studies which have reported more rapid increases in cell wall HRGPs in resistant than in susceptible genotypes in different host-pathogen interactions such as the cucumber – *Cladosporium cucumerinum* (Hammerschmidt et al. 1984), the tomato – *Fusarium oxysporum* f. sp. *radicis-lycopersici* (Benhamou et al. 1991), the tobacco – *Erysiphe cichoracearum* (Raggi 2000), the wheat – *F. culmorum* (Kang and Buchenauer 1995), and the rice – *F. graminearum*. The present results provide further support for the role of HRGPs in the defense mechanism of sorghum against fungal infection.
2003) and the pearl millet – *Sclerospora graminicola* (Shailasree et al. 2004) interactions.

HRGPs were extracted from cell walls by a harsher treatment using a combination of acid and ethanol. This procedure denatures most of the other proteins and in the preparations, up to 70% of the proteins may be HRGPs (Mellon and Helgeson 1982; Shailasree et al. 2004). SDS-PAGE analysis of the acid: ethanol extracted cell wall proteins after Coomassie blue staining showed several proteins with molecular weights of ~65, 45, 17, and 14 kDa (data not shown). Four proteins positively cross-reacted with the polyclonal antibody pAB-P/HRGPs (Deepak et al. 2007a). The pAB-P/HRGPs were raised against purified P/HRGPs (Deepak et al. 2007b). The reaction of these proteins in the present study with this antibody identifies them as HRGPs. However, a differential pattern of induction of these proteins to *C. sublineolum* infection in genotypes. SC146, SC326 and BTx623 were recorded. The levels of HRGPs, particularly the ~17 and 14 kDa proteins following inoculation with the pathogen in the leaves of genotype SC146, indicating a role for these HRGPs in the defense of sorghum against *C. sublineolum* infection.

HRGPs are implicated in wall strengthening by formation of intra- and inter-molecular cross-links that involve isodityrosine (IDT) links (Cooper and Varner 1984; Epstein and Lamport 1984; Fry 1986; Smallhood et al. 1995). Wojtaszek et al. (1995, 1997) suggested that oxidative cross-linking of O-glycosylated HRGPs occurs after pathogen infection and that depends on a pronounced oxidative burst. Although the molecular mechanisms for this process are still not known, the whole process strongly decreases solubility of HRGPs, which subsequently lose their extractability by salts and SDS (Bradley et al. 1992). The absence of the ~45 kDa protein in genotypes SC146 and SC326 after inoculation with the pathogen may indicate that it participates in the cross-linking of HRGPs in the presence of H$_2$O$_2$ and peroxidase. Increases in H$_2$O$_2$ accumulation in the resistant genotype SC146 and the intermediately resistant genotype SC326 (P. Basavaraju, N.P. Shetty, H.S. Shetty, E. de Neergaard and H.J.L. Jørgensen, unpublished results) and simultaneous absence of the ~45 kDa HRGP protein strongly support its potential involvement in the oxidative cross-linking in response to pathogen ingress. Further evidence for the role of H$_2$O$_2$ in cross-linking of monomeric extensins was provided by Ribeiro et al. (2006). They demonstrated that in cell walls of grapevine (*Vitis vinifera* cv. Touriga) callus, cell walls that H$_2$O$_2$ stimulated a rapid loss of monomeric GvP1, concomitant with increased accumulation of insoluble GvP1 amino acids and the cell walls showed resistance to digestion by fungal lytic enzymes. Their results hypothesized a cooperative action between the extensin network and the electrostatic interaction with other cell wall proteins in the extracellular matrix. It is important to elucidate the exact role of the ~45 kDa protein in the disease resistance, and therefore, we are further characterizing the ~45 kDa protein in the sorghum – *C. sublineolum* interaction.

The accumulation of HRGP in response to the *C. sublineolum* was investigated in sorghum by a tissue printing immunoblot technique. The observation of cell wall proteins by this technique was demonstrated at first by Cassab and Varner (1987). It is reported to be a quick and easy method for detecting proteins/HRGPs in different plant tissues (Keller et al. 1988; Fritz et al. 1991; Hood et al. 1991). The results obtained showed accumulation of HRGPs in a tissue-specific manner, being highest in the cell walls of epidermal cells and vascular bundles. The differential responses associated with the compatible and incompatible interactions may reflect differences in the ability of individual tissues to respond to a common signal. HRGP localization in vascular tissues is thought to form a part of the defense response designed to prevent spread of the pathogen through the vascular system. Localization of HRGPs in these cells indicates that they may act in facilitating and amplifying defense signals. A similar observation was reported by Narvaez-Vasquez et al. (Narvez-Vasquez et al. 2005), who identified three novel hydroxyproline glycopeptidase signals (LeHyp sys I II III) present in tomato leaves as components in signal transduction. These signals were synthesized in phloem cells and released after wounding, being transmitted across phloem cells and thereby amplifying defense signals, which result in activation of defense genes.

At infection sites the cell wall barriers like formation of papillae and calllose deposition were high in the resistant and the intermediately resistant genotypes compared to susceptible genotype BTx623 (P. Basavaraju, unpublished data). The presence of such structural reinforcements at the early stage of infection during the biotrophic stage constitute a strong barrier and also obstructs the formation of further structures like infection vesicles and primary hyphae of *C. sublineolum* as evidence in SC146 (P. Basavaraju, personal communication). Such barriers could lead to shortage of nutrients or water during the biotrophic phase of hemibiotrophy as these infection vesicles and primary hyphae are known to draw the nutrients across the host plasma membrane (Perfect et al. 2001; Oliver and Ipcho 2004). Here, we have demonstrated a correlation between pathogen arrest, H$_2$O$_2$ accumulation and HRGPs cross-linking at infection sites at 2 dai.

Our earlier results demonstrated that higher accumulation of H$_2$O$_2$ in the resistant than in the susceptible (P. Basavaraju, N.P. Shetty, H.S. Shetty, E. de Neergaard and, H.J.L. Jørgensen, unpublished results). H$_2$O$_2$ accumulation started as early as 1 day after inoculation with *C. sublineolum*, peaking by
2 dai. Furthermore, there was an increase in defense-related, apoplastic peroxidase activity in the resistant and the intermediary resistant genotypes of sorghum after inoculation with *C. sublineolum*, with a maximum increase at 2 dai. These observations, together with the results of the present study on accumulation of HRGPs and protein cross-linking, indicates that cross-linking of HRGPs in cell walls is an early defense response in sorghum against *C. sublineolum* infection.
